## Executive Summary

During each year from 2004 through 2009, discarded end-use products contained an average of approximately 87.2 million tons ${ }^{1}$ of ferrous material of which 65 million tons were recoverable scrap and 47.5 million tons were recovered, leaving 17.5 million tons of recoverable but unrecovered scrap.

After taking account of an average annual corrosion loss, 17.3 million tons were added each year to the national inventory of obsolete ferrous scrap.

After aggregating annual inventory additions from 2004 through 2009 and adjusting the end-of-year 2009 inventory to take account of cumulative corrosion losses, the national inventory of obsolete ferrous scrap stood at 1.18 billion tons as of December 31, 2009. Of this total, 103.9 million tons ( 9 percent) accumulated in the inventory since the end of 2003.

Discarded construction materials generated more recoverable obsolete ferrous scrap (33.2 percent) than any other end-use product category. Discarded automotive products, which were previously the leading source for recoverable scrap, continue to be a significant source, generating 30.4 percent of recoverable scrap generated from 2004 through 2009.

Additions to the inventory occurred in all nine U.S. Census districts. From 2004 through 2009, cumulative net additions to inventory occurred mainly in the South Atlantic and Pacific districts. More than one-third ( 34.8 percent) occurred in these two districts combined. In contrast, New England accounted for the smallest share ( 4.5 percent) of the cumulative increase in inventory.

We estimate that 448.7 million tons of obsolete ferrous scrap will be generated from 2010 through 2014 based on production and net imports of ferrous containing end-use products through 2009. Of this amount, 344.8 million tons will be recoverable.

[^0]
## 1. Introduction

In 1977, Nathan Associates Inc. conducted the first study of the national inventory of obsolete ferrous scrap, where inventory was defined as "potential reserves." ${ }^{2}$ Potential reserves are:

- Quantities, either known or inferred, of ferrous material existing in discarded products,
- Quantities of material in a condition allowing for immediate use, and
- Quantities recoverable with the use of existing technology at prices higher than current prices, but not significantly higher.

Implicit in this definition of potential reserves is recognition of a price-supply continuum. As the price of scrap increases, so too does the volume of obsolete ferrous scrap recovered from the inventory and supplied to the iron and steel industry.

Nathan Associates produced five updates to its original study. ${ }^{3}$ The first and second updated inventories to December 31, 1977 and 1979, respectively, and the third refined the scrap inventory model to incorporate new information before calculating the scrap inventory as of December 31, 1981. The fourth update incorporated revisions to government published export and import data to calculate inventory as of December 31, 1983 and revised year-end 1980 and 1981 inventories. The most recent update, which was completed in 2005, calculated the inventory through December 31, 2003. In the 2005 study, we undertook a thorough analysis of changes in the production of new iron and steel, ferrous content of end-use products, and trade flows.

In this update, we again analyzed each aspect of our inventory model, as well as short term changes in iron and steel and ferrous containing end-use product markets that have occurred since 2003. The most significant development since our 2005 study was the impact of the global recession on the production of iron and steel and the consumption of ferrous scrap.

[^1]- The recession that began in December 2007 has had a significant impact on the production of steel in the United States. Crude steel production decreased by 7.4 percent in 2008, and 30.4 percent in 2009, after increasing by 19.2 percent between 2004 through 2007. ${ }^{4}$ The decrease in steel production lowered domestic demand for ferrous scrap. Consumption of ferrous scrap in the United States fell by 27.3 percent in $2009 .{ }^{5}$
- Although product declined, the share of steel produced in electric arc furnaces (EAFs) has continued to increase, from 51 percent of total crude steel production in 2003 to 61.8 percent in 2009. Production of crude steel in EAFs accounted for 80 percent of total scrap consumption in $2008 .{ }^{6}$
- In our re-examination of net imports of end-use products ${ }^{7}$ containing ferrous material (Table 1), we again found the major categories to be automotive, construction materials, and industrial machinery.

[^2]In this report, we present our estimate of the inventory (potential reserves) of obsolete ferrous scrap as of December 31, 2009. Following this introduction, we discuss the basic underlying concepts relevant to our definition of inventory, describe the ferrous material flow through the economy, and present an overview of our inventory-estimating methodology (Chapter 2). We next describe the data required by our methodology, identify data sources,, and describe key components of the methodology in more detail (Chapter 3). We conclude with a presentation of our national estimate and its regional distribution (Chapter 4). Appendices contain all the underlying data and derivations necessary to replicate our analysis.

## 2. Methodology

## Basic Concepts

Inventory, in the normal business sense, implies a stock of on-the-shelf items that can be put into use at a chosen moment depending on demand. The "on-the-shelf" aspect of this definition is not appropriate for measuring the inventory of obsolete ferrous scrap.

For obsolete ferrous scrap, a more relevant definition of inventory can be formulated using the geologic concepts of resources and reserves. Resources are concentrations of natural deposits of elements in the earth's crust or under the sea existing in such a form that they can be extracted and used. Reserves are a subset of resources. Reserves consist of the natural deposits of elements whose extent and grade are known to a greater or lesser degree and whose physical natures are such that they may be extracted at a profit with existing technology at current prices.

However, these geologic concepts are not precisely applicable to ferrous scrap. The geologic definitions are relevant to natural deposits of elements that are presumed to exist but must be discovered in their geologic setting; measured as "proved" in terms of composition, grade, and quantity; and then recovered for current or future use or abandoned. Thus, these concepts have both technical-discovery and technical-economic dimensions.

The magnitude of the technical-discovery problem inherent in natural deposits is not inherent in ferrous scrap. Ferrous scrap is produced at mills and foundries in the production of iron and steel (home scrap), in the manufacture of ferrous-containing end-use products (prompt scrap), and when ferrous-containing end-use products reach the ends of their useful lives and are discarded (obsolete scrap).

Thus, it is the technical-economic dimension that is more relevant to a definition of ferrous scrap inventory. A three-part classification of the technical-economic dimension reveals the concept most appropriate for defining and measuring the inventory of obsolete ferrous scrap.

- Resources of obsolete ferrous scrap consist of the ferrous material in discarded end-use products located on the earth's surface or in land fills that exists in such a form that it is possible to recover, extract, and use the material;
- Potential reserves of obsolete ferrous scrap, which is a subset of resources, consist of material that is of known or inferred quantity, in a condition that allows for immediate use, and available for recovery within the constraints of known technology and higher but realistic prices;
- Reserves of obsolete ferrous scrap, which are a subset of potential reserves, consist of obsolete ferrous scrap that is economically recoverable at prevailing prices.

For several reasons, the concept of potential reserves is the most appropriate for defining the inventory of obsolete ferrous scrap. The broadest concept of resources, to have validity, must include difficult-to-access material that could be recovered only in emergency situations, for example, material in landfills that could be dug up and recovered to meet war-time needs. Moreover, defining the inventory of obsolete ferrous scrap using the broadest concept of resources would necessarily include material that would likely be of relatively low quality because of its destruction in secondary use, for example, iron used in copper cementation and material that has oxidized significantly. The recovery of such material would be highly uncertain. Regarding the narrowest concept of reserves, historical increases in ferrous scrap prices have resulted in significant increases in recoverable and recovered obsolete ferrous scrap. Hence, a definition of the inventory of obsolete ferrous scrap using the narrowest concept of reserves (which are based on current prices) would necessarily exclude historically significant amounts of obsolete ferrous scrap that became recoverable and were recovered at prices higher than were generally prevailing at the time. Potential reserves include material that is relatively accessible and offers the advantage of scrap, that is, it exists in a metallic state so that it can be recovered within a short time in situations when scrap demand is increasing and driving prices higher.

## Flow of Ferrous Material

Conceptually, the inventory of scrap may be thought of as a pool of material, the size of which fluctuates according to the rates of additions to and withdrawals from the pool. In the case of obsolete ferrous scrap, additions to the pool occur as ferrous-containing products are discarded. Withdrawals take place as scrap is recovered and recycled.

The approach taken in this study traces the flow of ferrous materials through the U.S. economy (see Figure 1). The flow begins with the production of pig iron, hot-briquetted iron (HBI), and direct-reduced iron (DRI) which is then used by mills and foundries to produce iron and steel products, which are used by manufacturers of ferrous containing end-use products, which are consumed and eventually discarded.

が戍楽の
Flow of Ferrous Material

SOURCES：U．S．Department of Commerce modified by Nathan Associates Inc．

Ferrous scrap is generated at three points in the material flow．Mills and foundries generate home scrap that is recycled within the mills and foundries．Manufacturers of ferrous－ containing end－use products generate prompt scrap that is recycled through the material flow．Consumers of ferrous－containing end－use products generate obsolete scrap as they discard the products that have reached the ends of their useful lives．

At each point in the flow where ferrous material is transferred from one state into another， losses occur．A small portion of prompt scrap goes out of the flow with shop floor sweepings． Many obsolete home appliances and containers end up in landfills．Rail roof supports in coal mines are trapped by subsidence．Military goods are shipped overseas and never returned to the United States．And ferrous material in discarded end－use products oxidizes．

Although there is no precise definition for measuring system losses，in our analysis we assumed that material is lost when the object containing it is disposed of in a dump，landfill， or abandoned mine；the secondary use of the material，such as iron used in copper cementation，is destructive to the material；and when the cost to collect and process the material is prohibitive because of its remote location or dispersion．

## Flow of Methodology

Our methodology consists of five major steps listed below and requires an initial benchmark estimate of the national inventory (potential reserves) of obsolete ferrous scrap. ${ }^{8}$

1. Estimate amount of ferrous material in annual U.S-production of ferrous-containing enduse products. Shipments from U.S. mills and foundries to U.S. manufacturers of 14 categories of end-use products are added to imports and adjusted downward to account for prompt scrap generated in the manufacture of end-use products.

Material 1 =Shipments of Ferrous Material from Domestic and Foreign Mills and Foundries to U.S. Manufacturers of FerrousContaining End-Use Products Prompt Scrap Generated in Manufacturing<br>$\qquad$<br>Material $2=$ Material $1-$ Material in Exported End-Use Products + Material in Imported End-Use Products<br>Jacturo<br>Material $2=$ Material $1-$ Material in Exported End-Use Products + Material in Imported End-Use Products material in end-use products exported from and imported into the U.S. economy. Foreign trade in each of the 14 end-use product categories is examined to determine whether net imports significantly affect the amount of ferrous material

Three categories are found to have significant net imports: automobiles, industrial machinery, and construction materials.
3. Estimate recoverable obsolete ferrous scrap generated annually from the discard of ferrous-containing end-use products. End-use products have a useful life. For example, paint containers are generally discarded within a year. In contrast, structural beams can have useful lives exceeding 80 years. Product life statistics (minimum, median, and maximum ages) are used to estimate annual rates at which ferrouscontaining end-use products are discarded. The amount of ferrous material in these discarded products is adjusted downward to account for losses from corrosion and wear and tear during product life as well as losses from discarded products that cannot be recovered, for example, products discarded in dumps or landfills.
4. Estimate annual net additions to the national inventory (potential reserves) of obsolete ferrous scrap. Annual net additions to inventory are calculated by subtracting the year's recovered obsolete ferrous scrap from the year's generated recoverable obsolete scrap and adjusting the difference downward to account for continuing

$$
\begin{aligned}
& \text { Recoverable Obsolete Ferrous Scrap = } \\
& \text { Material } 2 \text { in Discarded Products - } \\

& \text { Products }
\end{aligned}
$$

2. Adjust estimate as necessary to account for ferrous in end-use products consumed in the United States.
corrosion of the recoverable but not yet recovered scrap. At the end of any year the inventory of obsolete ferrous scrap will equal the year-end inventory of the prior year plus the current year's net addition to inventory.
3. Regionalize the national inventory. In the final step of the methodology, the national inventory (potential reserves) of obsolete ferrous scrap is disaggregated into nine U.S. Census Regions using statistics indicating the likely physical location of discarded products for each of the 14 end-use product categories.

## 3. Data Required by Each Step in the Methodological Flow

The volume of data required to estimate inventory is significant, requiring numerous sources. The specific data required in each step of the methodology, the sources from which we obtained these data, and details on intermediate calculations required in our methodology are described here for each step in the methodology.

## Step 1: Ferrous Material in U.S. Produced End-Use Products

Estimation of ferrous material in U.S. produced end-use products requires data on domestic shipments of ferrous material to manufacturers, imports of ferrous material used in manufacturing, and prompt scrap generation rates in manufacturing.

## MATERIAL SHIPPED TO MANUFACTURERS

Manufacturers of ferrous-containing end-use products obtain ferrous materials from domestic iron and steel mills and foundries, as well as foreign mills and foundries. Two sources provide data for estimating the total amount of ferrous material received by manufacturers of end-use products: the American Iron \& Steel Institute (AISI) and the publication Modern Castings.

## Domestic Mill Shipments and Net Imports

AISI publishes three series of statistics used in our analysis:

- Annual shipments from domestic mills to each of the 19 AISI-defined markets,
- Annual shipments by product and AISI-defined market, and
- Annual imports from foreign mills by product.

Mill product imports are not reported by AISI-defined market category. We must estimate imports by market. We do so using annual domestic shipments by product and market for the
years 2003 and 2009. The derivation is explained following the discussion of foundry shipment data and sources.

## Foundry Shipments and Net Imports

Our methodology requires domestic foundry shipments of for-sale products. In our 2005 study, production statistics were obtained from the U.S. Census Bureau's annual Current Industrial Report for iron and steel castings. However, this publication was discontinued after 2003. Production statistics for 2004 through 2008 were obtained from the annual Census of World Casting, which is published by the foundry magazine Modern Casting. The census has been conducted since 1967, and provides statistics on the production of iron (gray, ductile, and malleable) and steel castings in foundries for more than 30 countries. We compared the total production statistics from the Census of World Casting with those in the Current Industrial Report for the years 1998 through 2003 and found a cumulative difference of only 4 percent.

While the Census of World Casting provides total production figures for the United States, it does not distinguish between for-sale and own-use production. In order to derive the portion of total production that is for-sale for the years 2004 through 2008, we applied the percentage of for-sale production to total production during the period from 2000 through 2003 (84.2 percent). In addition, the Census of World Casting does not report statistics on the exports and imports of ferrous foundry products. In order to estimate the net imports for 2004 through 2008, we applied the percentage of net imports to total production over the period from 2000 through 2003 (2.3 percent).

Lastly, the Census of World Casting for 2009 production has yet to be published. Hence, we estimated for-sale production plus net imports in 2009 using the following methodology. First, for the years 2000 through 2008 we compared the year-over-year percentage difference in domestic shipments plus imports of steel with the year-over-year percentage difference in foundry products for-sale production plus net imports. We found these steel and foundry products percentage differences to be similar over time. Therefore, we estimated 2009 for-sale foundry production plus net imports by applying the 2008 to 2009 percentage difference in shipments plus imports of steel ( -45 percent) to 2008 foundry for-sale production plus net imports (see Appendix C, Table C-44 for all foundry data and their specific sources; allocation factors are in Table C-45; calculation of 2009 foundry shipments are in Table C-46).

## Distributing Mill and Foundry Shipments to End-Use Product Categories

Our methodology requires data on the ferrous content of each of 14 categories of ferrouscontaining end-use products which will eventually be discarded. Therefore, we must convert ferrous shipments by AISI-defined market into ferrous shipments by end-use product.

We begin with mill shipment imports. Recall that AISI reported imports by product only and domestic shipments by product and market. Using the 2003 and 2009 domestic shipments by product and market, we calculated distributions of domestic shipments of mill products by
market category in each of these years, and then used the distributions to allocate annual imports by product to annual imports by market. ${ }^{9}$ The results, data, and calculations are in Appendix C, Tables C-1 through C-43.

With mill shipments net of foreign trade now quantified by AISI-defined market category, we employ a four-stage process to distribute AISI market specific mill and foundry shipments net of foreign trade into our 14 categories of ferrous-containing end-use products. The process utilizes additional information previously provided by the U.S. Bureau of Mines.

In stage one, we aggregate AISI mill shipments and Census Bureau foundry shipments into the seven demand categories of the U.S. Bureau of Mines using (Table 2). Allocations of specific AISI and Census market categories sum to 100 percent, with the exception of industrial fasteners, only half of which are allocated to demand categories. ${ }^{10}$ For example, with respect to Census Bureau foundry shipments, 25 percent are allocated to transportation, 25 percent are allocated to construction, 35 percent are allocated to machinery, five percent are allocated to oil and gas, five percent are allocated to household appliances, and the remaining five percent are allocated to the "other" demand category.

In stage two, we disaggregate the seven Bureau of Mines demand category totals into our 14 end-use product categories. Five of the Bureau's demand categories map directly into our end-use product categories, but two (machinery and transportation) consist of more than one end-use category

| Bureau of Mines Demand Category | End-Use Product Category |
| :--- | :--- |
| 1. Appliances | 1. Consumer durables |
| 2. Containers/packaging/shipping material | 2. Containers |
| 3. Construction | 3. Construction materials |
| 4. Oil and gas | 4. Oil and gas materials |
| 5. Other | 5. Material not elsewhere classified |
| 6. Machinery | 6. Agricultural machinery |
|  | 7. Electrical machinery |
|  | 8. Industrial machinery |
|  | 9. Mining materials |
| 7. Transportation | 10. Aircraft and aerospace |
|  | 11. Automotive |
|  | Rail transportation |
|  | 12. Railroad equipment |
| 13. Railroad rails |  |

[^3]|  -•* |  |
| :---: | :---: |
| 1. Transportation | = Automotive <br> + Railroad <br> + Ship building and marine <br> + Aircraft <br> $+0.25 \times$ Steel service centers <br> $+0.25 \times$ Foundry shipments |
| 2. Construction | = Construction, including maintenance <br> + Contractor's products <br> $+0.25 \times$ Industrial fasteners <br> $+0.25 \times$ Steel service centers <br> $+0.75 \times$ Steel for converting and processing <br> $+0.60 \times$ Non-classified <br> $+0.25 \times$ Foundry shipments |
| 3. Machinery | $=$ Machinery and intustrial equipment and tools <br> + Electrical equipment <br> + Agricultural total <br> + Mining, quarrying, and lumbering <br> + Independent forging <br> $+0.60 \times$ Other domestic and commercial equipment <br> $+0.20 \times$ Steel service centers <br> $+0.25 x$ Industrial fasterners <br> $+0.35 \times$ Foundry shipments |
| 4. Oil and gas | = Oil and gas supply housed <br> + Oil and gas drilling <br> $+0.10 \times$ Steel for converting and processing <br> $+0.05 \times$ Foundry shipments |
| 5. Household applian | = Appliances <br> $+0.40 \times$ Other domestic and commercial equipment <br> $+0.15 \times$ Steel service centers <br> $+0.05 \times$ Foundry shipments |
| 6. Containers | = Containers |
| 7. Other | = Ordinance and military <br> $+0.15 \times$ Steel service centers <br> $+0.05 \times$ Foundry shipments <br> $+0.15 \times$ Steel for converting and processing <br> $+0.40 \times$ Non-classified |

In stage three, we disaggregate the machinery and transportation demand category totals into category components using AISI component shares of AISI group totals.
AISI Market Component
Agricultural
Electrical equipment
Machinery, industrial equipment, \& tools
Mining, quarrying, and lumbering
Aircraft and aerospace
Automotive
Rail transportation
Ship building \& marine equipment

In the fourth and final stage, we disaggregate rail transportation market shipments into the two end-use product categories it comprises: railroad equipment and railroad rails. The allocation is based on shares of railroad equipment and railroad rail value as reported by the American Iron and Steel Institute in its Annual Statistical Report (Appendix A, Table A-58).

These aggregations and disaggregations of data, as well as the final distributions of annual shipments by ferrous-containing end-use product category are presented in Appendix A. See Table A-59 for the final distribution; Tables A-4 through A-30 for data that are first aggregated into the seven Bureau of Mines demand categories ; and Table A-31 through A-57 for aggregations into demand categories and disaggregations into end-use product categories.

## PROMPT SCRAP

According to Hogan and Koelble, in 1974, prompt industrial scrap generated during the manufacture of ferrous-containing end-use products ranged from six percent to 31 percent of ferrous material consumed by manufacturers. ${ }^{11}$ Across all 19 AISI-defined destination markets for steel mill products, the average prompt scrap generation rate was 16.6 percent.

In our 2005 update, we reviewed the applicability of these rates, and found that a number of researchers have checked the prompt rates over the years and found them to be generally comparable to the 1974 rate. ${ }^{12}$ In addition, we found that the Steel Recycling Institute relies on the 1974 Hogan and Koelble estimates and considers them valid based on their knowledge of the industry, ${ }^{13}$ and USGS estimates a prompt scrap rate of 15 percent of all steel shipments. ${ }^{14}$

[^4]Since the publication of our 2005 study, we found prompt scrap rates ranging from 6 percent to 20 percent in a presentation in 2008 to the International Iron and Steel Institute (IISI). ${ }^{15}$

Given these findings and the unlikelihood that prompt scrap rates would have changed substantially since 2005, we have continued to use the prompt scrap generation rates estimated by Hogan and Koelble and used in our previous studies. ${ }^{16}$

Because Hogan and Koelble's prompt scrap generation rates are AISI market specific, we must distribute prompt scrap generated into our 14 categories of ferrous-containing end-use products. We do so in a process parallel to the process of distributing shipments of mill and foundry products (see Appendix A, Tables A-4 through A-30 for AISI data; Tables A-31 through A-57 for aggregations of AISI data into demand categories and disaggregations into end-use product categories; and Table A-60 for final estimates of product-specific prompt scrap generated annually in manufacturing).

## Step 2: Net Imports of End-Use Products Containing Ferrous Material

In our previous studies we determined that net imports of automotive, industrial machinery, and construction products were of sufficient magnitude to have effect on the potential reserves of obsolete ferrous scrap. After re-examining each of the product categories, we found that these three categories continue to be the only categories of significant effect on potential reserves. Our estimates of the ferrous content of net imports of these end-use products are in Appendix A, Table A-61. The underlying data are in Appendix E.

#### Abstract

AUTOMOTIVE Estimation of net imports of ferrous material contained in automotive products requires data on vehicles imported and exported and the ferrous content of those vehicles. Our analysis consists of three steps. First, we compute the number of vehicles (both passenger and commercial) exported from and imported into the United States. Second, we estimate the weight of these vehicles. Third, we estimate the proportion of the total weight that is ferrous material.

Numerous vehicle trade statistics are compiled by Wards Automotive in its annual Motor Vehicle Facts and Figures publication. With respect to passenger vehicles, Wards reports the

[^5]number of units of passenger vehicles exported and imported, but not vehicle weight. We used data maintained by the United States National Highway Traffic Safety Administration (NHTSA) to estimate weight. These NHTSA data contain the curb weight ${ }^{17}$ of each vehicle the NHTSA performs safety tests on. In addition, the data contain information on the make, model, and model year of each tested vehicle. To derive the annual export weight of U.S. manufactured passenger cars, in each year we calculate the average curb weight of the U.S. model cars tested by the NHTSA and apply these weights to the number of cars exported in that year.

With respect to imports of passenger vehicles, Wards reports the number of passenger vehicles imported by country of origin. We grouped these imports into five regions: Canada, Mexico, Japan, Germany, and Rest of World. For Canada and Mexico we applied the average curb weight of U.S. manufactured models in that year. For Japan, we identified the models produced by Japanese manufacturers, and calculated the average curb weight of those vehicles. The same process was followed for Germany and rest-of-world.

For commercial vehicles, Wards separates U.S. factory sales by weight class in each year. We apply this distribution to the number of commercial vehicles exported in that year to estimate the total export weight of commercial vehicles. Wards also reports retail sales of imported trucks and buses by weight class and manufacturer. We apply this distribution to the total number of imported commercial vehicles in each year to calculate the total import weight of commercial vehicles.

After computing the total weight of exported and imported passenger and commercial vehicles, it is necessary to adjust these weights downward to remove non-ferrous weight.

We rely on several sources to estimate the ferrous content of exported vehicles. Ferrous content of American manufactured passenger cars is reported in Motor Vehicle Facts and Figures. Through 2004 the statistics reported by Wards on ferrous content were developed by the American Metal Market (AMM). However, AMM discontinued their analysis after 2004. For the years 2004 to 2009, Wards reports data from the American Chemistry Council (ACC). We compared the ferrous content percentages from the AMM and ACC for 2003 and 2004 (two years of overlap) and found that the figures differed by only 0.3 percent and 0.2 percent, respectively. Hence, we use the ferrous content percentage from the ACC figures for the years 2005 through 2009. Wards does not provide statistics on the ferrous content of American manufactured trucks and buses. In the absence of these data, we applied the American passenger car ferrous percentages to the total weight of American manufactured exports of trucks and buses as reported by Wards Automotive. Although more specific data are

[^6]preferred, nearly two-thirds of truck and bus exports weigh less than 6,000 pounds, and these light trucks are relatively similar to passenger cars according to an industry expert. ${ }^{18}$

Information on the ferrous content of imported vehicles is sparse. As discussed in our 2005 study, there has been a general decline in ferrous content of automobiles as manufacturers have substituted aluminum for iron in engine blocks. For our 2005 study we consulted with an expert in the automotive and aluminum industries, and these consultations revealed that Japanese manufacturers began making this substitution five to 10 years earlier than American manufacturers. Europe also began substituting aluminum for iron earlier than America. ${ }^{19}$ Therefore, we assumed that the average Japanese car had the ferrous content of an American car produced 10 years later than the Japanese model year. For Europe and other countries, we used five years. On the basis of these trends, we estimated the ferrous content of imported automobiles, as well as trucks and buses, 95 percent of which weighed fewer than 6,000 pounds. We used this methodology here.

## INDUSTRIAL MACHINERY

The weight of industrial machinery imported and exported for 2004 through 2009 is calculated from international trade data maintained by the United Nations (COMTRADE). ${ }^{20}$ While COMTRADE reports the total weight of imports and exports, most industrial machinery contains non-ferrous materials. A 2007 material flow model published in Resources, Conservation and Recycling estimates a ferrous content of 71 percent for mechanical machinery in the United Kingdom. ${ }^{21}$ Hence, we have multiplied the total net import weight reported by COMTRADE by 0.71 to derive the ferrous weight of imports and exports of industrial machinery. ${ }^{22}$

## CONSTRUCTION MATERIALS

The net imports of construction materials were included for the first time in our 2005 study as we found that net imports grew steadily from 767,000 tons in 1983 to over three million tons in 2003. Net imports continued to increase until 2006, reaching 4.9 million tons, and then declined with the economic downturn to two million tons in 2009. As in our 2005 study, our annual net import figures of the ferrous content of imported construction materials were

[^7]calculated using data compiled by the American Iron and Steel Institute in its Annual Statistical Report.

## Step 3: Recoverable Ferrous Material in Discarded End-Use Products

Products are taken out of service (discarded) at the ends of their useful economic lives. The rates at which they are discarded can significantly affect the amount of obsolete ferrous scrap generated in any year.

## PRODUCT DISCARD RATES

The useful life of any ferrous containing end-use product can be considered probabilistic by nature. Seemingly identical products, such as the same car model produced on a common assembly line, can have different useful lives because of disparities in factors such as upkeep and frequency of use. Accidents, faulty construction, and misuse also influence the useful life of a product. This inherent uncertainty argues against assuming that all end-use products within a sector put into use in the same year will be discarded in the same year.

In our prior studies, we derived annual discard rates by fitting an S-shaped curve to statistics on the median and maximum lives of products. The shape of the curve was intended to represent the dynamics of product life.

Since our 2005 study, we have reviewed a number of academic studies that take a more advanced approach to modeling the process of product discard by using probability distributions. Modeling product lifetimes with probability distributions accounts for their uncertain nature. In addition, employing a probability distribution has the effect of smoothing the inflow of end-use products into the economy, which is believed to generate more realistic estimates of the quantity of discarded end-use products. ${ }^{23}$

Several probability distributions have been proposed to model product lifetimes. These include the Weibull, ${ }^{24}$ beta, ${ }^{25}$ and normal (Gaussian) distributions. ${ }^{26}$ The Weibull distribution has been found to provide a good fit for many different types of lifetime data analyzed in reliability engineering. ${ }^{27}$ The beta distribution is frequently used when there is little

[^8]information on the distribution of a random variable. ${ }^{28}$ The normal distribution has also been used in numerous end-of-life product studies. ${ }^{29}$ However, a prior study did not find substantial differences between these three distributions. ${ }^{30}$

In this study we use the normal distribution to model the useful lives of ferrous containing end-use products. In addition to the fact that prior studies have employed the distribution, we find the theoretical case compelling. Statistical theory demonstrates that the distribution of the mean of independent observations from any distribution is approximately normal. ${ }^{31}$ Thus, irrespective of the underlying distribution of product lifetimes, the distribution of the average lifetime follows the normal distribution.

To employ the normal distribution, information on the minimum, maximum, and median ${ }^{32}$ useful life is required for each end-use product category. In our 2005 study, we conducted a thorough review of the useful life literature, a detailed description of which can be found in the study. Our research for this study did not yield any new data that suggested we should change our lifetime parameters. However, the structure of the normal distribution requires us to make some modifications to the useful lives reported in our 2005 study.

The mathematical structure of the normal distribution requires that the minimum and maximum useful lives must be equidistant from the median. In several instances this would lead to a negative minimum useful life. Hence, we modified the median useful lives of some product categories. For aircraft, we modified the median useful life from 20 years to 30 years. For construction materials, the median useful life was modified from 32 years to 40.5 years. For materials not elsewhere classified, we modified the median useful life from 25 years to 27 years. In addition, the maximum useful life of automobiles was modified from 12.5 years in the 1980s and 16.9 years in the 1990s to 15 years. Table 3 lists the useful life parameters used in this study. Appendix D contains the mathematical derivations for modeling the useful lives using a normal distribution.

In addition to using this new methodology to estimate obsolete scrap generation for the years 2005 through 2009，we modified our estimates of obsolete scrap generation for the years 1983 through 2003 using this methodology．While the modification results in a cumulative difference of less than one percent compared to the figures reported in our 2005 study，we found that our new methodology estimates less generation in the early years of end－use product lives and is likely a more accurate reflection of the discard pattern of end－use products．

## UNRECOVERABLE MATERIAL IN DISCARDED PRODUCTS

Many end－use products are discarded in a manner or place that does not allow for recovery of their ferrous material．Indeed，some ferrous material in these products is lost forever．Thus， system losses must be taken into account when estimating the inventory of obsolete ferrous scrap．

The first system loss we account for occurs during use of ferrous-containing end-use products. Some ferrous material is lost through corrosion, wear, and tear. We continue to account for this component of loss by using a cumulative loss rate of one percent of the ferrous content of end-use products over the entire useful lives of the products. Hence, at the time of product discard, the ferrous content of the discarded product is 99 percent of the ferrous content of the newly produced product.

The second and more substantial system loss occurs following discard of ferrous-containing products. In this analysis, we continue to consider material in products disposed of in dumps or landfills, material destroyed in secondary use, and material in products discarded in remote locations as lost material.

Originally, to quantify this second type of system loss we examined studies by the Battelle Memorial Institute, A.T. Kearney, the U.S. Bureau of Mines, and the National Center for Resource Recovery. ${ }^{33}$ Our subsequent updates continued to rely on these studies for estimates of the amount of ferrous material in discarded end-use products that is unrecoverable. In our 2005 study we made one adjustment for ship building and marine equipment. Because vessels are scrapped and dismantled abroad, and not in the United States, the ferrous material in these discarded products is not recoverable. Hence, we modified the unrecoverable percentage to 100 percent for this product category.

After making this adjustment for ship building and marine equipment, the average percentage of obsolete ferrous scrap generated but not recoverable is 30 percent (Table 4).

Our 2005 report noted that the Steel Recycling Institute estimates that 12 percent of ferrous material in discarded products is unrecoverable. ${ }^{34}$ In the course of our work for this study, we found a 2005 International Iron and Steel Institute (IISI) report which estimates the unrecoverable rate to be 14.1 percent. ${ }^{35}$

Although both the SRI and IISI studies indicate that a higher percentage of obsolete ferrous scrap is available for recovery than our model suggests, we have opted to continue to use our recovery rates because they take a more conservative position on the amount of recoverable obsolete scrap.

The details of all quantities derived at this point in the methodology are in Appendix B, Tables B-1 through B-15. Ferrous shipments, prompt scrap generated, the ferrous content of end-use products consumed in the United States, obsolete scrap generated, and the obsolete scrap that is unrecoverable are presented annually for 1983 through 2009 by end-use product category and in total across all product categories.

## Step 4：National Inventory of Obsolete Ferrous Scrap

The end－of－2009 national inventory of obsolete ferrous scrap equals the end－of－1955 benchmark national inventory adjusted for continuing corrosion losses plus the cumulative annual net additions to the national inventory of obsolete ferrous scrap．

An annual net addition to the inventory of obsolete ferrous scrap occurs when the amount of generated and recoverable obsolete scrap exceeds the amount of recovered obsolete scrap． The excess must be adjusted downward to account for continuing loss of material from corrosion．So，at this point in our methodology，we need to estimate the annual amount of generated obsolete ferrous scrap that is recovered and the corrosion loss on net annual additions to inventory（see Appendix A，Table A－2 for estimates of annual net additions to inventory adjusted for corrosion losses）．

## RECOVERED OBSOLETE FERROUS SCRAP

The Minerals Yearbook and, more recently, the Minerals Industry Survey of the USGS provide statistics from which we calculate the amount of ferrous scrap recovered annually (see Appendix A, Tables A-4 through A-30). More specifically, the statistics include annual iron and steel scrap purchases, imports, and exports.

However, these statistics are not reported by end-use product category and they do not differentiate prompt scrap from obsolete scrap. Therefore, we must first estimate the amount of prompt ferrous scrap recovered annually and then subtract it from total ferrous scrap recovered annually to derive an estimate of obsolete ferrous scrap recovered annually. As in our last study we use a prompt scrap recovery rate of 98.5 percent, which is based on an internal study conducted by the Steel Recycling Institute in 2000. ${ }^{36}$

## CORROSION LOSSES

Corrosion losses continue to occur on inventoried obsolete ferrous scrap. Here and in our previous studies, we used an average corrosion rate of 0.36 percent per year, based on unpublished data provided by U.S. Steel.

## Step 5: Inventory by Region

In our final step, we disaggregate our estimate of the year-end 2009 national inventory of obsolete ferrous scrap into nine U.S. Census Regions. The disaggregation occurs for each of the 14 categories of ferrous-containing end-use products and each year. The disaggregation was accomplished using proxies likely to indicate the location of use and disposal for each product category. Census-region distributions of each proxy were calculated for each year and then used to allocate to regions the annual net additions to the national inventory.

For all end-use product categories, the proxies used in this update are the same as the proxies used in our 2005 study. Table 5 lists the proxy used for each end-use category, and the years for which the proxy is available. The footnotes denote the source for each, which are all government institutions or industry associations. Appendix F provides detailed data for regionalizing our national inventory estimate.

However, given the timing of this update not all proxy values are available yet for 2009. When values were not available for 2009, we relied on 2008 values.

## 4. Results

As of December 31, 2009 the national inventory of obsolete ferrous scrap was $1,179.9$ million tons (Table 6). Each year since December 31, 2003, the inventory has increased. The 2004 through 2009 cumulative increase after accounting for corrosion losses totaled 103.9 million tons or approximately 17.3 million tons per year. The average annual amount of generated and recoverable obsolete ferrous scrap was approximately 65 million tons. The average annual amount of obsolete scrap recovered was approximately 47 million tons. All annual amounts are in Appendix A, Table A-2.

Of the 14 ferrous-containing end-use products included in our analysis, the greatest amount of obsolete ferrous scrap was generated through the discard of construction materials (Table 7), followed closely by automotive products. More than half ( 53.7 percent) of all obsolete ferrous scrap generated from 2004 through 2009 was generated from discarded construction materials ( 29.1 percent) and automotive products ( 24.6 percent). As with our 2005 study, discarded aircraft and aerospace equipment generated the smallest amount of recoverable obsolete ferrous scrap ( 0.1 percent).

The national inventory is located throughout the country (Table 8). Approximately 32.7 percent of the inventory is located in the South Atlantic (16.5 percent) and East North Central (16.2 percent) districts combined. Another 29.1 percent is located in the West North Central and West South Central districts combined. This distribution is based on a weighted average of the distribution of proxies used in our previous analyses and the distribution of our current proxies.

Looking forward to the years 2010 through 2014, based on the ferrous containing end-use products entering the U.S. economy through 2009, we estimate 448.7 million tons of obsolete ferrous scrap will be generated, of which 344.8 million tons will be recoverable. Out of this recoverable obsolete ferrous scrap, 84.9 percent will be in the form of discarded construction materials, vehicles, and machinery. Table 9 details the recoverable obsolete ferrous scrap by product category for the years 2010 through 2014. It should be noted that these figures are conservative, as they do not reflect the discard of any end-use products that will enter the U.S. economy after 2009.

Summary of the National Inventory of Obsolete Ferrous Scrap as of December 31, 2009

| 5 | - $\square^{\text {¢ }}$ |

| Potential reserves as of December 31, 2009 |  |

[a] From Battelle Memorial Institute, Final Report on a Survey and Analysis of the Supply and Availability of Obsolete Iron and Steel Scrap, prepared for US Department of Commerce, BDSA, January 15, 1957.
[b] Equals $13.2 \%$ of the resource base of 1955. See the 1977 Nathan Associates report, page 77.
[c] Equal to 1955 base inventory subtotal multiplied by $0.36 \%$ and 37.5 years. See the 1977 Nathan Associates report, page 79.
[d] Equal to 1955 base inventory less adjustment for corrosion prior to 1956 multiplied by $0.36 \%$ and 28 years.
[e] Equal to 1955 base inventory less adjustment for corrosion prior to 1984 multiplied by $0.36 \%$ and 20 years.
[f] Equal to 1955 base inventory less adjustment for corrosion prior to 2004 multiplied by $0.36 \%$ and 6 years.
[g] From Table A-2.

Note：Data in columns［1］through［6］for the years 1956 through 1982 are from Iron and Steel Scrap：Its Accumulation and Availability Updated to December 31，1983，Nathan Associates Inc．，August 1984，Table 3.
［a］From Appendix B，Table B－15．
［b］Equals＂iron and steel scrap receipts purchases＂minus＂iron and steel scrap imports＂plus＂iron and steel scrap exports，＂all of which are in Tables A－4 through A－30 for years 1983 through 2009，respectively．
［c］Equals column［4］minus $98.5 \%$ of 3－year moving average of prompt scrap generated，which is from Appendix B，Table B－15．
［d］Equals column［6］multiplied by $0.36 \%$ and the difference between the year 2009 and the year of the change in inventory．

［a］Years 1921－1982 from Nathan Associates，Iron and Steel Scrap：Its Accumulation and Availability Updated to December 31，1983，August 1984；years 1983－2009 from Appendix B，Tables B－1 through B－14．
［b］ 1953 and 1954 equal to the average of 1955 to 1961.
［c］ 1929 through 1947 calculated using compound annual growth rate from 1948 to 1962.
［d］ 1902 through 1926 calculated using compound annual growth rate from 1927 to 1940.

SOURCES ：Generated obsolete scrap is calculated using statistical techniques that model the useful lives of ferrous containing end－use products by year of discard．See Appendix D，＂Mathematical
Derivations for Modeling the Useful Lives of Ferrous Containing End－Use Products＂．

Obosolete Ferrous Scrap Recovery Rates by End-Use Product, 1983-2009

|  |  |
| :---: | :---: |
| Automotive | 92\% |
| Ship building and marine equipment [a] | 0\% |
| Aircraft and aerospace | 99\% |
| Railroad equipment | 98\% |
| Railroad rails | 98\% |
| Industrial machinery | 88\% |
| Electrical machinery | 87\% |
| Mining materials | 75\% |
| Agricultural machinery | 70\% |
| Consumer durables | 9\% |
| Containers | 3\% |
| Oil and gas materials | 50\% |
| Materials not elsewhere classified | 60\% |
| Construction materials | 85\% |

[a] When ships are discarded, they are floated overseas and disassembled. They do not contribute to the reserves of recoverable obsolete scrap and are considered entirely unrecoverable.

[a] All values for years 1983-1984 from US Census Bureau, Current Industrial Reports, Series MA33A, Table 1A. Subtotal for years 1985-1986 from US Census Bureau, Statistical Abstract of the US, 1991, Table No. 1331; subtotal for year 1987-1995 from US EPA, Economic Impact Analysis of Proposed Iron and Steel Foundries NESHAP, November 2002, Table 2-11. For Sale and For Own Use for 1985-1995 calculated using averages from 1996-2003 from Appendix Table C-45. All values for years 1996-2003 from US Census Bureau, Current Industrial Reports, Series MA331A(03)-1, Table 3 . Subtotal for years 2004-2008 taken from Census of World Casting Production 2004-2008 respectively. For Sale and For Own Use for 2004-2008 calculated using averages from 2000-2003 from Appendix Table C-45
[b] Subtotal for years 1985-1996 calculated using average from years 1997-2003 from Appendix Table C-45. All values for years 1983-1984 from US Census Bureau, Current Industrial Reports, Series MA33, Table 6; all values for years 1997-2003 from US Census Bureau, Current Industrial Reports, Series MA331A(03)-1, Table 4. Subtotal for years 2000-2004 calculated using average from years 2000-2003 from Appendix Table C-45
[c] Equal to Imports minus Exports.
[d] Equal to Domestic Production: For Sale plus International Trade: Subtotal
[e] Total foundry shipments for 2009 is estimated using the annual growth rate of iron and steel shipments (domestic and imported) by steel mills for 2009. See Appendix C, Table C-46.

Calculation of Foundry Shipments, 2009 (thousand net tons)

|  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |

[a] From Appendix C, Table-1 and Table-2.
[b] 2000 through 2008 values from Appendix C, Table-44. Domestic foundry shipment takes into account "For Sale" domestic production only. Trade accounts for net imports (Imports minus Exports).
[c] 2009 foundry shipment is calculated by applying the Iron and Steel Shipments annual growth rate for 2009 to Foundry Shipments for 2008. Estimated total foundry shipment for 2009 is used in Appendix C, Table C-44.

## Appendix D

Derivation of Probability Density Functions for Modeling the Useful Lives of Ferrous-Containing End-Use Products

## Appendix D

Derivation of probability density functions for modeling the useful lives of ferrous-containing end-use products

Lifetimes of ferrous containing end-use products are considered to follow the normal (or Gaussian) distribution. The normal distribution has the probability density function (pdf) in equation (1).

$$
\begin{equation*}
\mathrm{f}(\mathrm{t}, \mu, \sigma)=\left[\frac{1}{\sigma \cdot(\sqrt{2 \cdot \pi})}\right] \mathrm{e}^{\frac{-(\mathrm{t}-\mu)^{2}}{2 \cdot \sigma^{2}}} \tag{1}
\end{equation*}
$$

$t$ is time in years, $\mu$ is the average lifetime, and $\sigma$ is the standard deviation. $\mu$ is set equal to the average lifetimes listed in Table 2. $\sigma$ is derived based on properties of the normal distribution and the maximum lifetimes parameters listed in Table 2.

It can be shown that $99.7 \%$ of the area of the normal distribution is within three standard deviations of the mean. Hence, if we set the maximum life to be exactly three standard deviations away from the mean, we ensure that virtually 100 percent of ferrous content is discarded between the minimum $(\mathrm{min})$ and maximum (max) values. Either the minimum or the maximum value is sufficient to find the standard deviation. Using the maximum value, the standard deviation can be found using algebra:

$$
\begin{equation*}
\max =\mu-3 \cdot \sigma \Rightarrow \sigma=\frac{1}{3} \cdot \mu-\frac{1}{3} \cdot \max \tag{2}
\end{equation*}
$$

Because the normal distribution is symmetric around $\mu$, it follows that:

$$
\begin{equation*}
\mu=\frac{\min +\max }{2} \tag{3}
\end{equation*}
$$

Substituting (3) for $\mu$ in (2) we can solve for $\sigma$ :
$\sigma=\frac{1}{3} \cdot \frac{\min +\max }{2}-\frac{1}{3} \cdot \min =\left(\frac{\min +\max }{6}\right)-\frac{2 \min }{6}=\frac{\min +\max -2 \min }{6}=\frac{\max -\min }{6}$
Using equation (4), we can calculate $\sigma$ for each of the thirteen end-use product categories, excluding containers. Containers do not enter the life-time analysis because they have a maximum life of one year. Table D-1 shows the mean and standard deviation for each of the thirteen product categories. The mean and standard deviation define a unique normal probability density function.

## Table D-1

Probability Density Parameters by End-Use Product Category

| Fategory Name | Minimum <br> Useful life | Average <br> [Median] <br> Useful Life | Maximum <br> Useful Life | Mean [и] | Standard <br> Deviation [d] |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | $(1)$ | $(2)$ | $(3)$ | $(4)=(2)$ | $(5)=[(3)-(1)] / 6$ |
| Agricultural machinery | 11 | 23 | 35 | 23 | 4.0 |
| Aircraft and aerospace | 0 | 30 | 60 | 30 | 10.0 |
| Automotive | 0 | 15 | 30 | 15 | 5.0 |
| Construction materials | 0 | 40.5 | 81 | 40.5 | 13.5 |
| Consumer durables | 8 | 18 | 28 | 18 | 3.3 |
| Electrical machinery | 13 | 24 | 35 | 24 | 3.7 |
| Industrial machinery | 13 | 24 | 35 | 24 | 3.7 |
| Materials, nec | 0 | 27 | 54 | 27 | 9.0 |
| Mining materials | 2 | 6 | 10 | 6 | 1.3 |
| Oil and gas materials | 2 | 16 | 30 | 16 | 4.7 |
| Railroad equipment | 0 | 19 | 38 | 19 | 6.3 |
| Railroad rails | 25 | 40 | 55 | 40 | 5.0 |
| Ship building and marine equipment | 24 | 32 | 32 | 2.7 |  |

The probability density functions are applied by product category and year to the ferrous material in end-use products entering the U.S. economy to determine the amount of ferrous material discarded in future years. The distributions are applied as follows:

Let $\mathrm{FM}_{s, t}$ be the ferrous material (FM) in product category $s$ entering the U.S. economy in year $t$. The probability density function (PDF) for a product category $s$ is given by:

$$
\begin{equation*}
\operatorname{PDF}(\mathrm{s})=\mathrm{f}\left(\mathrm{t}, \mu_{\mathrm{s}}, \sigma_{\mathrm{s}}\right)=\left[\frac{1}{\sigma_{\mathrm{s}} \cdot(\sqrt{2 \cdot \pi})}\right] \mathrm{e}^{\frac{-\left(\mathrm{t}-\mu_{\mathrm{s}}\right)^{2}}{2 \cdot \sigma_{\mathrm{s}}^{2}}} \tag{5}
\end{equation*}
$$

Where $\mu_{s}$ and $\sigma_{\mathrm{s}}$ are the product category specific means and standard deviations listed in Table D-1. The proportion of $\mathrm{FM}_{s, t}$ that is discarded in a future year $y$, is given by the area under the probability density function during that period, calculable with the integral:

$$
\begin{equation*}
\int_{\mathrm{n}}^{\mathrm{n}+1}\left[\frac{1}{\sigma_{\mathrm{s}} \cdot(\sqrt{2 \cdot \pi})}\right] \mathrm{e}^{\frac{-\left(\mathrm{t}-\mu_{\mathrm{s}}\right)^{2}}{2 \cdot \sigma_{\mathrm{s}}{ }^{2}}} \mathrm{dt} \tag{6}
\end{equation*}
$$

For each of the values of $\mathrm{FM}_{s, t}$ in our study (for 89 years and 13 product categories), we determine the quantity discarded in each future year $y$, denoted $D_{s, t, y}$, by calculating the following:

$$
\begin{equation*}
\mathrm{D}_{\mathrm{s}, \mathrm{t}, \mathrm{y}}=\mathrm{FM}_{\mathrm{s}, \mathrm{t}} \int_{(\min +\mathrm{i})}^{(\min +\mathrm{i}+1)}\left[\frac{1}{\sigma_{\mathrm{s}} \cdot(\sqrt{2 \cdot \pi})}\right] e^{\frac{-\left(\mathrm{t}-\mu_{\mathrm{s}}\right)^{2}}{2 \cdot \sigma_{\mathrm{s}}^{2}}} \mathrm{dt} \tag{6}
\end{equation*}
$$

For $\mathrm{i}=0 \ldots(\max -\min -1)$. The year of discard, $y$, is: $y=(t+\min +i)$.

After performing these calculations for all values of $\mathrm{FM}_{s, t}$, we adjust the figure downward by $1 \%$ to account for losses during use (corrosion and wear and tear). We then sum by product category and year of discard to calculate product category specific obsolete scrap generation in each year. These figures are in Appendix A, Table A-63.

[a] Trucks and Bus units for 1983 through 2003 are derived by multiplying average 1986 through 1997 weight class percentage in Table E-5 by total units, which are from Table E-11. For 2004 through 2009, these units are
derived by multiplying the weight class percentages of respective years in Table E-5 by total units, which are form Table E-11.
[b] From Table E-11.
[c] From Table E-3.
[d] Derived by multiplying units in weight class interval by mid-point of weight class interval ( 6,000 pounds in first interval and 33,001 pounds in last interval) and ferrous content percentage.
SOURCES : See footnotes.

 derived by multiplying the weight class percentages of respective years in Table E-5 by total units, which are form Table E-11
[b] From Table E-11
[c] From Table E-3.
[d] Derived by multiplying units in weight class interval by mid-point of weight class interval ( 6,000 pounds in first interval and 33,001 pounds in last interval) and ferrous content percentage.

[a] Trucks and Bus units for 1983 through 2003 are derived by multiplying average 1986 through 1997 weight class percentage in Table E-5 by total units, which are from Table E-11. For 2004 through 2009, these units are derived by multiplying the weight class percentages of respective years in Table E-5 by total units, which are form Table E-11.
[b] From Table E-11.
[c] From Table E-3.
[d] Derived by multiplying units in weight class interval by mid-point of weight class interval ( 6,000 pounds in first interval and 33,001 pounds in last interval) and ferrous content percentage.

[a] Trucks and Bus units for 1983 through 2003 are derived by multiplying average 1986 through 1997 weight class percentage in Table E-5 by total units, which are from Table E-11. For 2004 through 2009 , these units are derived by multiplying the weight class percentages of respective years in Table E-5 by total units, which are form Table E-11.
[b] From Table E-11.
[c] From Table E-3.
[d] Derived by multiplying units in weight class interval by mid-point of weight class interval ( 6,000 pounds in first interval and 33,001 pounds in last interval) and ferrous content percentage. SOURCES : See footnotes.

## Table E-14

Ferrous Content of Car Exports Using MVFF Vehicle Data,
1983-2009 [a]

| Year [b] | Average <br> Vehicle <br> Weight [pounds] [al [1] | Average Vehicle Ferrous Content Weight [pounds] [2] | Ferrous <br> Content Weight Share $[3]=[2] \div[1]$ |
| :---: | :---: | :---: | :---: |
| Based on American Metal Market |  |  |  |
| 1983 | 3,173.0 | 2,256.5 | 71\% |
| 1984 | 3,232.0 | 2,299.5 | 71\% |
| 1985 | 3,187.5 | 2,250.5 | 71\% |
| 1986 | 3,170.5 | 2,245.0 | 71\% |
| 1987 | 3,178.0 | 2,234.5 | 70\% |
| 1988 | 3,167.0 | 2,205.0 | 70\% |
| 1989 | 3,140.0 | 2,187.0 | 70\% |
| 1990 | 2,896.0 | 1,962.0 | 68\% |
| 1991 | 3,015.8 | 2,050.3 | 68\% |
| 1992 | 3,135.5 | 2,138.5 | 68\% |
| 1993 | 3,149.5 | 2,138.0 | 68\% |
| 1994 | 3,171.0 | 2,147.0 | 68\% |
| 1995 | 3,208.0 | 2,165.5 | 68\% |
| 1996 | 3,236.0 | 2,170.0 | 67\% |
| 1997 | 3,248.0 | 2,168.0 | 67\% |
| 1998 | 3,261.5 | 2,169.0 | 67\% |
| 1999 | 3,274.0 | 2,157.5 | 66\% |
| 2000 | 3,286.0 | 2,140.0 | 65\% |
| 2001 | 3,309.0 | 2,125.5 | 64\% |
| 2002 | 3,357.5 | 2,141.5 | 64\% |
| 2003 | 3,358.5 | 2,141.5 | 64\% |
| Based on American Chemistry Council |  |  |  |
| 2004 | 4,034.0 | 2,564.0 | 64\% |
| 2005 | 4,017.0 | 2,559.0 | 64\% |
| 2006 | 4,044.0 | 2,561.0 | 63\% |
| 2007 | 4,076.0 | 2,593.0 | 64\% |
| 2008 | 4,070.0 | 2,562.0 | 63\% |
| 2009 | 4,070.0 | 2,562.0 | 63\% |

Note: "na" means not applicable.
[a] In previous table (Table E-13), the NHTSA NCAP database was used instead of the MVFF data.
[b] Vehicle and material weights for 1983 and 1991 equal average weights for the previous and following years; 2009 vehicle and material weights equal to 2008
SOURCES: Motor Vehicle Facts and Figures , 1981-1987, 1989-1996, 20002003, 2004-2010; U.S. Census Bureau for exports; and Al Wrigley, Automotive Material Content (Received from AISI - not published as
received).

| 2003 | 336,092 | 657,180 | 0.5114 | na | na |
| Total | na | na | 0.693787 | na | na |

Note: "na" means not applicable.
[a] Ratio equal to the sum of reported units divided by the sum of calculated units for 1986-1990. A graphical
analysis of the time period, showed reported units tracking calculated units relatively closely, at a lower level, during this time.
[b] Calculated truck and bus exports are derived from total and domestic factory sales data.

Note: The U.S. Census Bureau reports waterborne trade weight (vessel weight), waterborne trade value (vessel value), and total trade value (customs value), but not total trade weight which is required to estimate weight of ferrous
content in traded end-use products. This worksheet derives ratios of trade customs value to trade vessel value for 2002 and 2003 and then applies those ratios to waterborne trade weight statistics from the U.S. Army Corps of Engineers to
latate total (all tranportation modes) trade weight. See Table E-22 for the derivations.
a) Used in Table $\mathrm{E}-22$ to calculate total exports and imports of industrial machinery.

SOURCE: U.S. Census Bureau.

[a] Equals recoverable scrap from Appendix B, Table B-1 multiplied by appropriate percentage from Table F-23.
[b] When ships are discarded, they are floated overseas and disassembled. Hence, ferrous content in discarded products in the ship building and marine equipment category does not enter into recoverable obsolete ferrous scrap inventory.
[c] Equals recoverable scrap from Appendix B, Table B-3 multiplied by appropriate percentage from Table F-24.
[d] Equals recoverable scrap from Appendix B, Table B-4 multiplied by appropriate percentage from Table F-25, [e] Equals recoverable scrap from Appendix B, Table B-5 multiplied by appropriate percentage from Table F-25. [f] Equals recoverable scrap from Appendix B, Table B-6 multiplied by appropriate percentage from Table F-26. [g] Equals recoverable scrap from Appendix B, Table B-7 multiplied by appropriate percentage from Table F-26. [h] Equals recoverable scrap from Appendix B, Table B-8 multiplied by appropriate percentage from Table F-27. [i] Equals recoverable scrap from Appendix B, Table B-9 multiplied by appropriate percentage from Table F-28. [j] Equals recoverable scrap from Appendix B, Table B-10 multiplied by appropriate percentage from Table F-29. [k] Equals recoverable scrap from Appendix B, Table B-11 multiplied by appropriate percentage from Table F-30. [1] Equals recoverable scrap from Appendix B, Table B-12 multiplied by appropriate percentage from Table F-31. [ m ] Equals recoverable scrap from Appendix B, Table B-13 multiplied by appropriate percentage from Table F-30. [n] Equals recoverable scrap from Appendix B, Table B-14 multiplied by appropriate percentage from Table F-32. SOURCES: See footnotes.

[a] Equals recoverable scrap from Appendix B, Table B-1 multiplied by appropriate percentage from Table F-23.
[b] When ships are discarded, they are floated overseas and disassembled. Hence, ferrous content in discarded products in the ship building and marine equipment category does not enter into recoverable obsolete ferrous scrap inventory.
[c] Equals recoverable scrap from Appendix B, Table B-3 multiplied by appropriate percentage from Table F-24.
[d] Equals recoverable scrap from Appendix B, Table B-4 multiplied by appropriate percentage from Table F-25, [e] Equals recoverable scrap from Appendix B, Table B-5 multiplied by appropriate percentage from Table F-25. [f] Equals recoverable scrap from Appendix B, Table B-6 multiplied by appropriate percentage from Table F-26.     ${ }^{3}$ Robert R. Nathan Associates, Inc., Iron and Steel Scrap: Its Accumulation and Availability Updated to December 31, 1977, 1979, 1981, 1983, and 2003 Metal Scrap Research and Education Foundation, Washington, D.C., August 25, 1978, October 10, 1980, December 23, 1982, August 1984, and July 2005 respectively.

[^2]:    ${ }^{4}$ Based on crude steel production figures published in 2009 Annual Statistical Report, American Iron \& Steel Institute (AISI).
    ${ }^{5}$ Mineral Commodity Summaries, U.S. Geological Survey, January 2010.
    ${ }^{6} 2009$ Annual Statistical Report, American Iron \& Steel Institute (AISI).
    7 Prior to our 2005 study, our analyses considered 15 ferrous-containing end-use product categories. In our 2005 study, we combine statistics on (1) agricultural machinery and (2) other agricultural materials into the single agricultural machinery category. Hence, for this update we continue to use 14 end-use product categories.

[^3]:    ${ }^{9}$ The 2003 distribution was used to allocate 2004 through 2008 imports. The 2009 distribution was used to allocate 2009 imports. We did not interpolate distributions for years in which we did not have actual data.
    ${ }^{10}$ We gross up shipments by end-use category to include the remaining half of industrial fasteners.

    16 Note that the prompt scrap generation rates of Hogan and Koelble are reported by AISI-defined market categories. Hence, the prompt scrap rates for each of our 14 categories of ferrous-containing end-use products are averages of the Hogan and Koelble rates weighted by our final distribution of AISI-reported shipments into our 14 end-use product categories.

[^6]:    17 Curb weight is the weight of a vehicle with a full gas tank and no passengers or cargo.

[^7]:    18 Personal communications with Dick Schultz, Project Consultant with Ducker Worldwide, previously the President of Alcoa Automotive Structures and the Director of Worldwide Automotive Products for Alcoa in Southfield, Michigan.

    21 ,J. Davis et. al., "Time-dependent material flow analysis of iron and steel in the UK. Part 2: Scrap generation and recycling," Resources, Conservation and Recycling 51 (2007).
    ${ }^{22}$ In our 2005 study, we did not adjust the total weight of the exports and imports of industrial machinery downward to account for the weight of non-ferrous materials. We have rectified this by adjusting the total weight of the net imports of industrial machinery for the years 1983 through 2003, with the same methodology used for the years 2004 through 2009.

    ${ }^{30}$ M.T. Melo, "Statistical analysis of metal scrap generation: the case of aluminum in Germany," Resources, Conservation and Recycling 26 (1999) , compares the normal, Weibull, and beta distributions; and,J. Davis et. al., "Time-dependent material flow analysis of iron and steel in the UK. Part 2: Scrap generation and
    recycling," Resources, Conservation and Recycling 51 (2007), compares the Weibull and beta distributions.
    ${ }^{31}$ This is the Central Limit Theorem. See, for example, DeGroot and Schervish, "Probability and Statistics," $3^{\text {rd }}$ edition, Addison-Wesley, 2002, pp. 282-290.
    ${ }^{32}$ Because the normal distribution is symmetric the median is equal to the mean (or average). Hence, the median lifetimes used in our prior studies can be used as the mean in this discard analysis.
